#### Definition (Fréchet (1948))

A point  $x_0$  in a metric space  $(\mathbf{M}, \rho)$  is called a Fréchet mean of a (finite) measure  $\mu$  on  $\mathbf{M}$  if the Fréchet function

$$F_{\mu}(x) = \frac{1}{2} \int_{\boldsymbol{M}} \rho(x, y)^2 d\mu(y)$$

achieves its global minimum at  $x_0$ .

We shall always assume that  $F_{\mu}$  is finite at least at one point to ensure the existence of Fréchet means and that  $\mu$  has a unique Fréchet mean.

- Fréchet means generalize Euclidean means.
- SLLN holds for Fréchet means (Ziezold (1977)).

< 1 k

- Fréchet means generalize Euclidean means.
- SLLN holds for Fréchet means (Ziezold (1977)).
- There is generally no closed form for Fréchet means: they are implicitly defined.
- In practice, they are usually estimated by iterative algorithms.
- The iterative algorithms can be very slow, e.g. in the case of phylogenetic trees.

Given  $X_1, \dots, X_n$ : *iid* random variables on *M* with sample Fréchet mean  $\hat{X}_n$  and (common) distribution  $\mu$ , which has Fréchet mean  $x_0$ .

Inference on means is often linked with CLT:

In the case  $\boldsymbol{M} = \mathbb{R}^m$ , if

$$\sqrt{n}{\hat{X}_n - x_0} \stackrel{\mathsf{d}}{\longrightarrow} N(0, \Gamma),$$

then  $\Gamma = \operatorname{cov}(X_1)$  and

$$\|\Gamma^{-1/2}(\hat{X}_n-x_0)\|^2 \stackrel{d}{\longrightarrow} \chi^2(m).$$

・ 同 ト ・ ヨ ト ・ ヨ

The case when M is a Riemannian manifold:

#### Theorem

Under certain technical conditions,

$$\sqrt{n} \exp_{\mathbf{x}_0}^{-1}(\hat{X}_n) \stackrel{d}{\longrightarrow} \mathcal{N}(0, E[H_{\mathbf{x}_0, \mathbf{X}_1}]^{-1} \Gamma E[H_{\mathbf{x}_0, \mathbf{X}_1}]^{-\top})$$

as  $n \to \infty$ , where

$$\Gamma = \operatorname{cov}(\exp_{x_0}^{-1}(X_1)),$$

and  $H_{x,y}$  is a map on the tangent space at x, defined by

$$H_{x,y}: v \mapsto -D_v \exp_x^{-1}(y).$$

(Cf. Bhattacharya & Patrangenaru (2005); Bhattacharya & Bhattacharya (2008); Kendall & Le (2011).)

10/38

• As 
$$n o \infty$$
,

$$\frac{1}{\sqrt{n}}\sum_{i=1}^{n}\exp_{x_{0}}^{-1}(X_{i})\stackrel{\mathsf{d}}{\longrightarrow}\mathsf{N}(0,\Gamma).$$

• For fixed y,  $H_{x,y}$  is closely linked to the Hessian of  $\rho(x, y)^2$ .

∃ >

12

Difficulties in using the CLT for inference of Fréchet means:

- needs the estimation of  $E[H_{x_0,X_1}]$ ;
- involves the 'technical' condition:

$$\lim_{r \to 0} \mathsf{E} \left[ \sup_{x \in \mathrm{B}(x_0, r)} \left\| H_{x, X_1} - H_{x_0, X_1} \right\| \right] = 0,$$

arising due to the 'delta' method used in the proof.

Difficulties in using the CLT for inference of Fréchet means:

- needs the estimation of  $E[H_{x_0, X_1}]$ ;
- involves the 'technical' condition:

$$\lim_{r \to 0} \mathsf{E} \left[ \sup_{x \in \mathrm{B}(x_0, r)} \left\| H_{x, X_1} - H_{x_0, X_1} \right\| \right] = 0,$$

arising due to the 'delta' method used in the proof.

If the support of the distribution of  $X_1$  is *not* disjoint from  $C(x_0)$  (the cut locus of  $x_0$ ), the 'technical' condition does not generally hold.

The von Mises distribution on the circle is such an example.

BUT, this 'technical' condition can be removed at a price:

#### Theorem

If **M** is a compact manifold and if the distribution of  $X_1$  has a continuous density  $f_{X_1}$  (w.r.t. to volume measure) in a neighbourhood of  $C(x_0)$ , then

$$\sqrt{n} \exp_{x_0}^{-1}(\hat{X}_n) \stackrel{d}{\longrightarrow} N(0, \mathsf{E} \, [\Phi_{x_0, X_1}]^{-1} \, \mathsf{\Gamma} \, \mathsf{E} \, [\Phi_{x_0, X_1}]^{-\top})$$

as  $n \to \infty$ , where

$$\Phi_{x_0,X_1} = \mathsf{E}[H_{x_0,X_1}] + J_{x_0,X_1}.$$

*J* is an integral of the distribution over a 'nice' *co-dimension one* subset of  $C(x_0)$ , where the integrand depends on the nature of the relationship between  $x_0$  and  $C(x_0)$ .

- 本間 と く ヨ と く ヨ と 二 ヨ

Three examples:

1.  $M = S^1$  (Hotz & Huckemann (2015)):

$$J_{0,X_1} = -2\pi f_{X_1}(\pi).$$

2.  $\boldsymbol{M} = S^1 \times S^1$  (the flat torus):

$$J_{(0,0),X_1} = -2\pi \left( \begin{matrix} \int_{-\pi}^{\pi} f_{X_1}(y_1,\pi) \, \mathrm{d} \, y_1 & 0 \\ 0 & \int_{-\pi}^{\pi} f_{X_1}(\pi,y_2) \, \mathrm{d} \, y_2 \end{matrix} \right).$$

3

3.  $M = RP^2$ :

$$J_{(0,0),X_1} = -\pi \int_0^{\pi} \begin{pmatrix} \cos^2 \theta & \sin \theta \cos \theta \\ \sin \theta \cos \theta & \sin^2 \theta \end{pmatrix} f_{X_1}(\pi/2,\theta) \ \mathrm{d} \, \theta.$$

• 
$$J_{x_0,X_1} = 0$$
 on  $S^m$  if  $m > 1$ .  
•  $J_{x_0,X_1} = 0$  if  $f_{X_1} = 0$  on  $C(x_0)$ .

æ

In summary:

using the CLT for inference of Fréchet means requires a lot of work estimating the relevant covariance matrix.

Assume that **M** is an open book.

**Case 1:** the Fréchet mean  $x_0$  lies within a page (say page 1).

Then, the CLT resembles that on manifolds:

Theorem (Hotz et.al. (2013))

$$\sqrt{n}{\hat{X}_n - x_0} \longrightarrow N(0,\Gamma)$$

as  $n \to \infty$ , where  $\Gamma = \operatorname{cov}(F_1(X_i))$  and  $F_k$  is the so-called folding map:

- For fixed k,  $F_k(X_i)$  are Euclidean r.v.'s.
- For general stratified spaces,
  - *F<sub>k</sub>* are replaced by the *log map*;
  - for the covariance matrix in the CLT, Γ needs to be multiplied on both sides by another component, arising from the derivative of the log map.

**Case 2:** the Fréchet mean  $x_0$  lies on the spine.

Then, it is either *sticky* i.e.

 $\hat{X}_n$  lies on the spine for all sufficiently large n, or *partly sticky* i.e.

 $\hat{X}_n$  lies either on the spine or within a particular page for all sufficiently large n

(cf. Hotz et.al. (2013)).

- For the sticky case, the limiting distribution of  $\sqrt{n}{\hat{X}_n x_0}$  is Gaussian with support on the spine.
- For the partly sticky case,

►

$$P(\hat{X}_n \text{ lies on the spine}) \longrightarrow \frac{1}{2};$$

• the limiting distribution of  $\sqrt{n}\{\hat{X}_n - x_0\}$  is no longer Gaussian, but still related to a Gaussian distribution.

In summary:

in addition to the issues highlighted for manifolds, Fréchet means behave in a non-classical way if they are on the spine (co-dimension one subspace).

Empirical likelihood (cf. Owen (2001))

- is a non-parametric method of statistical inference;
- combines non-parametric methods with likelihood approach;
- uses mainly optimization algorithms for computation.

Empirical likelihood (cf. Owen (2001))

- is a non-parametric method of statistical inference;
- combines non-parametric methods with likelihood approach;
- uses mainly optimization algorithms for computation.

For a given set of *i.i.d* data  $X_1, \dots, X_n$  in  $\mathbb{R}^m$ , the non-parametric likelihood  $L(\mu)$  for a distribution  $\mu$  on  $\mathbb{R}^m$  is defined as

$$L(\mu)=\prod_{i=1}^n \mu(\{X_i\}).$$

Then, use  $L(\mu)$  to define

$$R_n(\mu)=\frac{L(\mu)}{L(\mu_n)},$$

where  $\mu_n$  denotes the empirical distribution of  $X_{1, \vdots, \cdot}, X_{n \cdot \cdot \cdot \cdot}$ 

Finally, for a given family of distributions  $\mathcal{P},$  the empirical likelihood for means is defined as

$$\mathcal{R}_n(x) = \sup\{R_n(\mu) \mid \text{ mean of } \mu = x, \ \mu \in \mathcal{P}\}.$$

If we choose  $\mathcal{P}$  to consist of all distributions taking values in  $\{X_1, \dots, X_n\}$ , then  $\log(\mathcal{R}_n(x))$  for  $x \in \mathbb{R}^m$  is the solution of the following optimization problem:

$$\max \sum_{i=1}^{n} \log p_{i} \qquad \text{subject to} \begin{cases} \sum_{i=1}^{n} p_{i} = 1, \ p_{i} \ge 0; \\ \sum_{i=1}^{n} p_{i} X_{i} = x. \end{cases}$$

Empirical likelihood hypothesis tests reject  $H_0$ : mean of  $\mu_0 = x_0$ , when  $\mathcal{R}_n(x_0) < r_0$  for some threshold value  $r_0$ .

The threshold  $r_0$  may be chosen using an empirical likelihood theorem, a non-parametric analogue of Wilks' theorem (cf. Owen (2001)):

Let  $X_1, \dots, X_n$  be i.i.d. random variables on  $\mathbb{R}^m$ . Let  $x_0 = E[X_1]$ , and suppose that  $cov(X_1)$  is positive definite. Then

$$-2\log(\mathcal{R}_n(x_0)) \stackrel{\mathsf{d}}{\longrightarrow} \chi^2(m)$$

as  $n \to \infty$ .

## EL for Fréchet means on manifolds

When **M** is a Riemannian manifold:

The Fréchet mean  $x_0$  of a distribution  $\mu$  on **M** must satisfy

$$\int_{\boldsymbol{M}} \exp_{x_0}^{-1}(y) \, d\mu(y) = 0.$$

 This gives us a link between Fréchet means of X and Euclidean means of exp<sup>-1</sup><sub>x0</sub>(X):

if X on **M** has Fréchet mean  $x_0$ , then the Euclidean random variable  $\exp_{x_0}^{-1}(X)$  has its Euclidean mean at the origin of the tangent space at  $x_0$ .

 If *M* is complete, simply-connected and of non-positive curvature, the above is also sufficient for x<sub>0</sub> to be the Fréchet mean of μ.

#### EL for Fréchet means on manifolds

The above link with Euclidean r.v.'s leads us to consider the EL for the critical points of Fréchet functions:

$$\mathcal{R}_n(x) = \sup\left\{R_n(\mu) \mid \int_{\boldsymbol{M}} \exp_{x_0}^{-1}(y) d\mu(y) = 0, \ \mu \in \mathcal{P}
ight\}.$$

Treat this as the EL for Fréchet means.

Then, on  $\mathbf{M} \setminus \bigcup_{i=1}^{n} C(X_i)$ , it corresponds to the solution of the optimization problem:

$$\operatorname{og}(\mathcal{R}_n(x)) = \max \sum_{i=1}^n \log p_i,$$
  
subject to 
$$\begin{cases} \sum_{i=1}^n p_i = 1, \ p_i \ge 0; \\ \sum_{i=1}^n p_i \exp_x^{-1}(X_i) = 0. \end{cases}$$

# EL for Fréchet means on manifolds

#### Theorem

Assume that  $X_1, \dots, X_n$  are i.i.d. random variables on **M** with Fréchet mean  $x_0$ . Then,

$$-2\log(\mathcal{R}_n(x_0)) \stackrel{d}{\longrightarrow} \chi^2(m)$$

as  $n \to \infty$ .

Since this only involves Euclidean random variables, we have avoided the need for estimation of the extra terms in the covariance in CLT.

Care is required:

•  $\log(\mathcal{R}_n)$  is not necessarily a concave function on M.

(4) (日本)

For simplicity, we concentrate on open-books.

Without loss of generality, we assume that the support of  $\mu$  has non-empty intersection with all pages.

For simplicity, we concentrate on open-books.

Without loss of generality, we assume that the support of  $\mu$  has non-empty intersection with all pages.

**Case 1:** the Fréchet mean  $x_0$  of  $\mu$  lies within a page. Then

 $x_0$  is the Fréchet mean of  $\mu$  $\Leftrightarrow x_0$  is the critical point of  $F_{\mu}$ .

For simplicity, we concentrate on open-books.

Without loss of generality, we assume that the support of  $\mu$  has non-empty intersection with all pages.

**Case 1:** the Fréchet mean  $x_0$  of  $\mu$  lies within a page. Then

 $x_0$  is the Fréchet mean of  $\mu$  $\Leftrightarrow$   $x_0$  is the critical point of  $F_{\mu}$ .

This leads us to define, for x lying within a page, the EL for Fréchet means to be

 $\mathcal{R}_n(x) = \sup \{ R_n(\mu) \mid x \text{ is the critical point of } F_\mu, \ \mu \in \mathcal{P} \}.$ 

イロト 不得下 イヨト イヨト 二日

**Case 1**: the Fréchet mean  $x_0$  of  $\mu$  lies within a page, say page 1.

Then,  $x_0$  is characterized by

$$\int_{\boldsymbol{M}} F_1(y) \, d\mu(y) = x_0.$$

Thus, the EL for Fréchet means on page k satisfies

$$\log(\mathcal{R}_n(x)) = \max \sum_{i=1}^n \log p_i$$
  
subject to 
$$\begin{cases} \sum_{i=1}^n p_i = 1, \ p_i \ge 0;\\ \sum_{i=1}^n p_i F_k(X_i) = x.\\ \vdots = 1 \end{cases}$$

 $log(\mathcal{R}_n)$  is a concave function on each page, but is generally discontinuous when crossing the spine:

#### Theorem

Assume that  $X_1, \dots, X_n$  are i.i.d with distribution  $\mu$  and that the Fréchet mean  $x_0$  of  $\mu$  is not on the spine. Then

$$-2\log(\mathcal{R}_n(x_0)) \stackrel{d}{\longrightarrow} \chi^2(m)$$

as  $n \to \infty$ .

- 3

< □ > < □ > < □ > < □ > < □ > < □ >

**Case 2:** the Fréchet mean  $x_0$  is on the spine.

Then,  $x_0$  is characterized by

$$\int_{M} P_{S}(x) d\mu(x) = P_{S}(x_{0})(=x_{0}) \text{ and}$$
$$\int_{M} \langle F_{j}(x), e_{j} \rangle d\mu(x) \leq 0, \quad j = 1, \cdots, \ell,$$

where  $P_S$  denotes the projection to the spine and  $e_j$  denotes the 'outward' unit vector that is tangent to page j and is orthogonal to the spine.

Under our assumption, the inequalities above can include at most one equality.

(人間) トイヨト イヨト ニヨ

This characterization implies that the logarithm of the corresponding EL optimization problem on the spine becomes more complicated:

$$\operatorname{subject} \operatorname{to} \left\{ \begin{array}{l} \max \sum_{i=1}^{n} \log p_{i}, \\ \sum_{i=1}^{n} p_{i} = 1, \ p_{i} \ge 0; \\ \sum_{i=1}^{n} p_{i} P_{S}(X_{i}) = x; \\ \sum_{i=1}^{n} p_{i} \langle F_{k}(X_{i}), e_{k} \rangle \leqslant 0, \quad k = 1, \cdots, \ell. \end{array} \right.$$

However, this can be simplified using knowledge of the sample Euclidean means of  $F_k(X_i)$ .

It is known that

either

(i) there is (only one) k say k = 1, such that the sample mean of  $F_1(X_1), \dots, F_1(X_n)$  is on page 1;

or

(ii) otherwise.

#### Proposition

For case (i) with k = 1, the constraint optimization problem associated with the EL for Fréchet means on the spine is equivalent to the following

$$\max \sum_{i=1}^{n} \log p_i \qquad subject \ to \ \begin{cases} \sum_{i=1}^{n} p_i = 1, \ p_i \ge 0; \\ \sum_{i=1}^{n} p_i F_1(X_i) = x. \end{cases}$$

#### Proposition

If x is on the spine and is sufficiently close to  $\hat{X}_n$  then, for case (ii), the constraint optimization problem associated with the EL for Fréchet means is equivalent to the following

$$\max \sum_{i=1}^{n} \log p_i \qquad \text{subject to} \begin{cases} \sum_{i=1}^{n} p_i = 1, \ p_i \ge 0; \\ \sum_{i=1}^{n} p_i P_S(X_i) = x. \end{cases}$$

#### Theorem

Assume that the Fréchet mean  $x_0$  of  $\mu$  is on the spine. Then, as  $n \to \infty$ ,

$$-2\log(\mathcal{R}_n(x_0)) \stackrel{d}{\longrightarrow} \begin{cases} \frac{1}{2} \{\chi^2(m) + \chi^2(m-1)\} & \text{if } x_0 \text{ is partly sticky} \\ \chi^2(m-1) & \text{if } x_0 \text{ is sticky.} \end{cases}$$
